Assignment Instructions

We would like you to take our test assignment as a challenge and next step. We've attached the Rails project where we would like you to focus on backend architecture and system design. The frontend is not a priority in this exercise.

Additionally, we would like you to write the code without using AI. While we generally support and embrace proper use of relevant AI tools for efficiency in development work, it makes it difficult to directly assess your personal structure and preferences when producing code, in a test assessment. *Hence, please do not provide code which has effectively been produced primarily with the use of AI.*

In this project, we're using the mentioned Rails Event Store stack (https://railseventstore.org/) as an event streaming platform. This robust, open-source tool has successfully handles around 3 million annual transactions on Billetto. We've also included a brief document summarizing the Rails Event Store approach.

If you prefer, you may consider an alternative DDD (Domain-Driven Design) approach if you believe it provides a better solution. However, our production environment relies heavily on Rails Event Store, so familiarity with it will be beneficial. Our main focus is on backend architecture, system design, performance, scalability, and effectively handling side effects.

The expectation isn't for you to complete the entire project from end to end, but rather to demonstrate attention to detail and quality in the areas mentioned above. We don't expect you to spend days solving this - we recommend that you "timebox" and provide us with insights into your problem solving abilities as well as communication around this if needed.
